Abstract- In a world that is more digitally connected than ever before, keeping your personal data safe is essential..Currently, Voice over Internet Protocol (VoIP) becomes one of the most dominant and attracting technologies in the world of telecommunications. The two major issues in VoIP is to be consider are that , the confidential data falling in the hands of network attackers and remembering of long cryptographic keys .Here we propose to generate a biometric key using iris, which is the combination of the iris code and the pseudo random numbers as a key for VoIP Communication. This iris key act as a symmetric key for both encryption and decryption. Unfortunately if the iris biometric is stolen, this makes the attacker to access the data if the data encrypted with biometric key alone. To overcome this problem we propose to use pseudo random numbers, which is fused with iris biometric. Therefore billions of unique keys can be generated, making VoIP technology hard for an attacker to guess the key .This proposed system is composed of two modules 1)Feature extraction of Iris 2)Cryptographic key generation.

Index Terms- Biometrics, Cryptosystem, Iris Extraction, Minutiae point, fusion.

1. INTRODUCTION

Today with exponential increase of **Voice over Internet Protocol** (VoIP) technologies it arises as dominant technology in the World of telecommunications. Because it allows any person to make a phone call through internet connection.

1.1 VoIP Communication:

In VoIP technology, the voice signal is first separated into frames, which are then stored in data packets, and finally it transport over IP network using voice communication protocol [1]. Usually both the caller and callee send and receive phone call over the internet.

Security issues are most important and integral part of VoIP applications development. The main obstacles that prevent VoIP businesses are the security issues that prevailed in this technology, i.e. the hackers/intruders can intercept incoming and outgoing phone numbers, break in someone's voice mail, or even listen to the confidential conversations over IP networks [2].Many research organizations are trying to tackle the issue to have a secured VoIP communication. Instead of being the digital information is packetized and transmitted over a network, these data packets are encrypted and decrypted by Biometric cryptosystems make secure transmission.

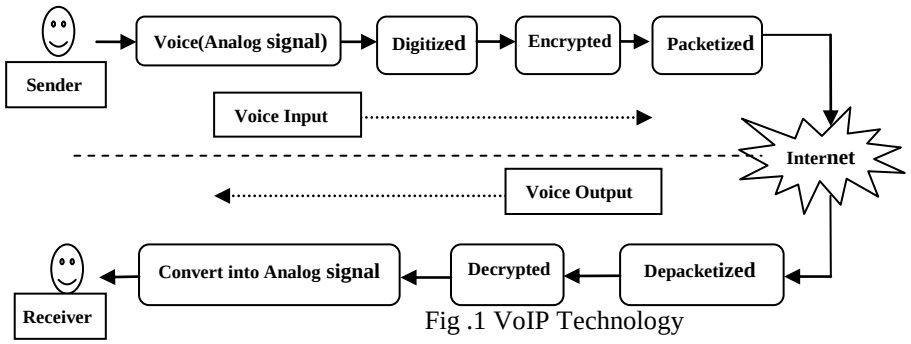

Fig .1 VoIP Technology

1.2. Biometric Encryption

This is the one of the safest way to provide confidentiality and integrity to the VoIP data.

Biometric technique [3] provides the distinct characteristics of a person which is always prevalent. A person's individuality can be differentiated from one or more behavioral or physiological features by this authentication technique. Various techniques that are under the biometric research include facial, palm facial, palm prints, retinal and iris scans, and hand geometry, signature capture and vocal features [4]. Biometric-Crypto system is a method of integrating biometrics features with cryptographic system [5]. In this biometrics-based key generation technique, a biometric input is obtained. From the unique biometric identity of a person, the keys can be generated, and with the help of these keys the VoIP data can be encrypted.

1.3. Iris Biometric Key Generation:

Among the biometric key generation methods iris biometric is considered to be one of the most accurate and robust. The iris is an externally visible, yet protected organ whose unique epigenetic pattern remains stable throughout adult life. These characteristics make it very attractive for use as a biometric for identifying individuals. Iris features can be easily extracted from eye images [6].Each individual has a uniquely different and highly intricate iris pattern in each eye, which is completely developed at a very young age and remains unchanged throughout one's lifetime. This is combined with the fact that iris patterns are almost impossible to replicate, makes iris scanning one of the most secure and reliable biometric techniques available. Image processing techniques can be employed to extract the unique iris pattern from a digitized image of the eye, and encode it into a biometric template, which can be stored in a database. Here John Daugman's iris recognition algorithm is used to generate iris code. He invented the IrisCode, a 2D Gabor wavelet-based iris recognition algorithm that is the basis of all publicly deployed automatic iris recognition systems and which has registered more than a billion persons worldwide in government ID programs. This biometric template contains an objective mathematical representation of the unique information stored in the iris code.

2. LITERATURE REVIEW

The proposed work is inspired from a number of researches which are related to biometric cryptography key generating techniques. The VoIP calls are also vulnerable to hijacking or a man in the middle attack. In such a scenario, an attacker would intercept a connection and modify call parameters. This is an especially scary attack, since the participants likely wouldn't notice a change. One way to help protect your privacy is to encrypt these conversations so that they aren't simply floating around out there for potential hackers to latch onto [11]. An algorithmic function's strength and the key's secrecy determine how secure the encrypted data is. In most cases, the algorithm isn't the secret; it's known to the public. The secret is the key. Values taken from the biometric and combine with a random sequence forms the keys for encryption/decryption. John Daughman algorithm resulted with the genuine iris codes with a 99.5 percent achievement rate, which upshot with 140 bits of biometric key which is sufficient for a 128-bit AES. In the current development, biometric cryptosystems [12] take advantage from the strong points of both fields. In such systems, while cryptography endows with high and modifiable security levels, biometrics provides non-repudiation and removes the requirement to memorize passwords or to carry tokens [13].Since Human iris possesses genetic independence and contains extremely information-rich physical structure and unique texture pattern which makes it highly complex enough to be used as a biometric signature. Statistical analysis reveals that the iris is the most mathematically unique feature of the human body because of the hundreds of degrees of freedom it gives with the ability to accurately measures its texture [14]. Reliable biometric verification and identification techniques based upon iris patterns have been presented by John Daugman [15], Wildes et al. [16], Boles [17]. One important characteristic of the iris is that, it is so unique that no two irises are alike, even among identical twins, in the entire human population [18]. The human iris, an annular part between the pupil (generally, appearing black in an image) and the white sclera has an extraordinary structure and offers a plenty of interlacing minute characteristics such as freckles, coronas, stripes and more. These visible characteristics, which are generally called the texture of the iris, are unique to each subject [19].

In cryptography, the use of pseudorandom number generators is insecure. When random values are required in cryptography, the goal is to make a message as hard to crack as possible, by eliminating or obscuring the parameters used to encrypt the message (the key) from the message itself or from the context in which it is carried [20]. Pseudorandom sequences are deterministic and reproducible; all that is required in order to discover and reproduce a pseudorandom sequence is the algorithm used to generate it and the initial seed. To overcome this difficulty we are fusing

the pseudo random sequence with the biometric iris code which will be more secure for data that transmit over open unsecure network.

3 .PROPOSED APPROACH FOR GENERATING A BIOMETRIC IRIS KEY

The proposed system includes five main modules: 1) Biometric image acquisition, 2) Segmentation , 3) Iris Normalization, 4)Feature point extraction of iris 5)Key Generation. The algorithm is based on the methods given by Daugman [15] .The proposed solutions for each of these modules are described in the following subsection with more detail.

3.1. Biometric Image Acquisition:

In the iris recognition process the first step is the image acquisition of a person's eye. The eye image is captured in the near infrared light with the wavelengths between 700–900 nm. Usually special infrared illuminators and band pass lens filters are used to acquire a image of good quality. The infrared light reveals the detailed structure of the iris better than the visible [15].

3.2. Segmentation

Iris segmentation is an essential module in iris recognition because it defines the effective image region used for subsequent processing such as feature extraction. Generally, the process of iris segmentation is composed of two steps 1) Estimation of iris boundary and 2) Noise removal.Below figure.1 the process of iris code extraction from an iris image. Figure 1 Iris code Extraction process

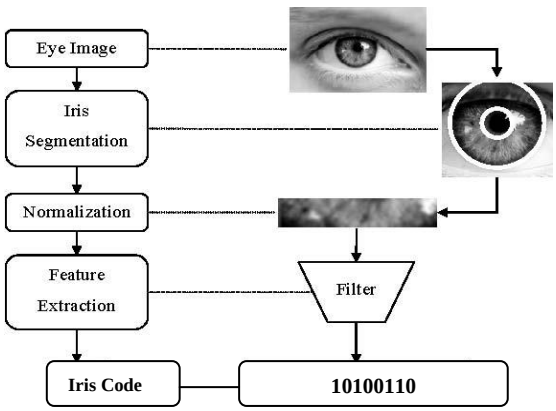

Fig. 1 Iris code Extraction process

Estimation of iris boundary: For boundary estimation, the iris image is first fed to the canny algorithm which generates the edge map of the iris image. The detected edge map is then used to locate the exact boundary of pupil and iris using Hough transform.

Canny edge detection The Canny edge detection operator was developed by John F. Canny in 1986. It uses a multi-stage algorithm to detect a wide range of edges in images. Canny edge detection starts with linear filtering to compute the gradient of the image intensity distribution function and ends with thinning and thresholding to obtain a binary map of edges. One significant feature of the Canny operator is its optimality in handling noisy images as the method bridges the gap between strong and weak edges of the image by connecting the weak edges in the output only if they are connected to strong edges. Therefore, the edges will probably be the actual ones. Hence compared to other edge detection methods, the canny operator is less fooled by spurious noise [21].

Hough Transform

The classical Hough transform was concerned with the identification of lines in the image, but later, the Hough transform has been extended to identify positions of arbitrary shapes, most commonly circles or ellipses. From the edge map obtained, votes are cast in Hough space for the parameters of circles passing through each edge point. These parameters are the centre coordinates *x* and *y*, and the radius *r*, which are able to define any circle according to the equation,

$x^2 + y^2 = r^2$

A maximum point in the Hough space will correspond to the radius and centre coordinates of the circle best defined by the edge points.

Isolation of Eyelids and Eyelashes: In general, the eyelids and eyelashes occlude the upper and lower parts of the iris region. In addition, specular reflections can occur within the iris region corrupting the iris pattern. The removal of such noises is also essential for obtaining reliable iris information. Eyelids are isolated by fitting a line to the upper and lower eyelid using the linear Hough transform. A second horizontal line is then drawn, which intersects with the first line at the iris edge that is closest to the pupil; the second horizontal line allows maximum isolation of eyelid region. The eyelashes are quite dark compared with the surrounding eyelid region. Therefore, thresholding is used to isolate eyelashes.

3.3. Iris Normalization:

Once the iris image is efficiently localized, then the next step is to transform it into the rectangular

sized fixed image. The transformation process is carried out using the Daugman's Rubber Sheet Model.

- Daugman's Rubber Sheet Model: Normalization process involves unwrapping the iris and converting it into its polar equivalent. It is done using Daugman's Rubber sheet model[21] and is shown in *figur*e2.

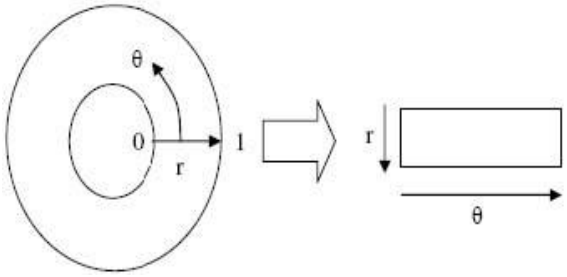

Figure 2. Daugman's Rubber Sheet Model

For every pixel in the iris, an equivalent position is found out on polar axes. The process comprises of two resolutions: Radial resolution, which is the number of data points in the radial direction and Angular resolution, which is the number of radial lines generated around iris region. Using the following equation, the iris region is transformed to a 2D array with horizontal dimensions of angular resolution and vertical dimension of radial resolution.

$$I\,[\,x\,(r\,,\,\theta\,),\,y(r\,,\,\theta\,)] \rightarrow I\,(r,\theta\,)$$

Where, $I\,(x,\,y)$ is the iris region, $(x,\,y)$ and $(r\,,\,\theta\,)$ are the Cartesian and normalized polar coordinates respectively. The range of θ is $[0\ 2\pi\ ]$ and r is [0 1]. $x(\,r\,,\,\theta\,)$ and

$y(\,r\,,\,\theta\,)$ are defined as linear combinations set of pupil boundary points. The formulas given in the following equations perform the transformation,

$$x(r,\theta\,) = (1-r)x_p\,(\theta\,) + x_i\,(\theta\,)$$

$$y(r,\theta\,) = (1-r)\,y_p\,(\theta\,) + y_i\,(\theta\,)$$

$$x_p\,(\theta\,) = x_{p0}\,(\theta\,) + r_p\,Cos\,(\theta\,)$$

$$y_p\,(\theta\,) = y_{p0}\,(\theta\,) + r_p\,Sin\,(\theta\,)$$

$$x_i\,(\theta\,) = x_{i0}\,(\theta\,) + r_i\,Cos\,(\theta\,)$$

$$y_i\,(\theta\,) = y_{i0}\,(\theta\,) + r_i\,Sin\,(\theta\,)$$

where (x_p,y_p) and (x_i,y_i) are the coordinates on the pupil and iris boundaries along the θ direction, =($x_{p0,}$ y_{p0}), ($x_{i0,}$ y_{i0}) are the coordinates of the pupil and iris centers[21].

3.4. Feature point Extraction of iris:

The normalized 2D form image is broken up into 1D signal, and these signals are used to convolve with 1D Gabor wavelets. The frequency response of a Log-Gabor filter is given as,

$$G(f) = \exp\left(\frac{-(\log(f/f0))^2}{2(\log(\sigma/f0))^2}\right)$$

Where f_0 represents the centre frequency, and σ gives the bandwidth of the filter [21]. The Log-Gabor filter outputs the biometric feature (texture properties) of the iris.

3.5. Key Generation:

Our basic design depends on two factors1) a biometric and 2) PRN Generators. If the biometric becomes known, this does not help the attacker, because the key is randomly generated. We make the key completely independent of the iris biometric, as this cannot be kept very secret. However, it is still costly to steal an iris code [23]. A near-infrared camera is needed and it is difficult to capture a person's iris image close-up without being noticed; most likely, iris code thefts will be conducted using subverted equipment in apparently genuine settings. In such a threat model, the attacker would get a password too, if one were in use; so we must rely completely on the token being tamper-resistant. In the following section, a key generation system is depicted based on the algorithm using minutiae points of iris biometric and pseudo random numbers.

Algorithm Assumptions:

Mp → Minutae point set
Kl → Key Length
Np → Size of minutae point set
S → Seed value
Sl → Seed limit
M → (x, y) coordinate of a minutae point
Kv → Key vector

Steps involved:

Step 1: Representation of the minutiae points extracted:

Mp {mi}i = 1.....Np (1)

Step 2: Definition of the key vector (initial):

Kv = {xi : p(xi)} where, i = 1 ... Kl

p(x) = Mp[I % Np] + Mp[(i + 1) % Np] + S (2)

Step 3: The changing values of S is given as follows where the initial value equals the number of minutiae points:

S = Kv(i) % S1, -1 < i < Kl (3)

Step 4: Conversion of the key vector (Kv) to a matrix

Km of size $\frac{Kl}{2} * \frac{Kl}{2}$ as follows ;

$K_{m=}\frac{(aij)Kl}{2} * \frac{Kl}{2}$

Step 5: Generation of the key vector (intermediate):

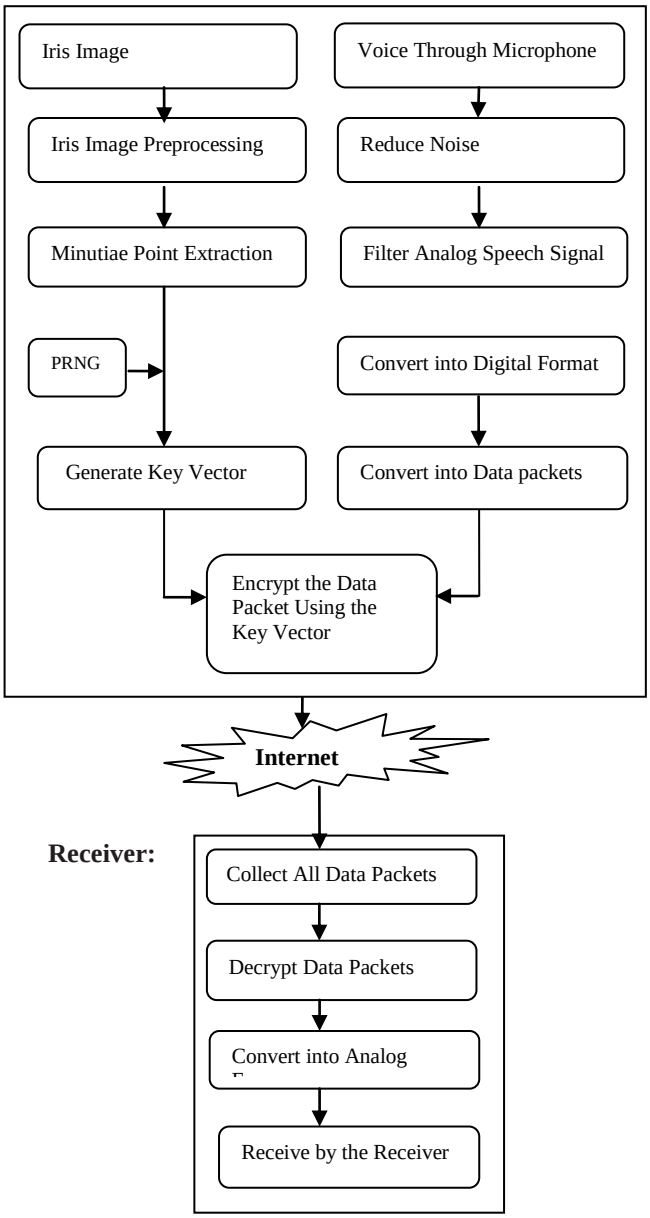
KIV = {Ki : (m(Ki)} where, i = 1.... .....Kl,

m(k)=$|A_{ij}|$,$A_{ij=}K_m$ I,j ; i+ size, j+ size,

$-1< i < \frac{Kl}{2}$ (5)

Note: The submatrix Aij is generated from the key matrix

Sender:



Step 6: Generation of the private key (final key vector):

Kv = 1, if KIV[i] > mean (KIV), else 0 (6)

Thus the key have generated for cryptography process for VoIP network using minutiae points of an individual's iris. Here we tackled the most difficult problem of merging cryptography with biometrics. On the basis of this system, it may be inferred that an attacker, in case of a biometric cryptosystem, will be unable to generate a key without having the complete knowledge of the key.

4. CONCLUSION

With the increasing need for secure transmissions over unsecured channels, the integration of biometrics with cryptosystem has become one of the secure channels for passing the confidential data. Thus the proposed method encrypts voice packets biometrically, to have a secured VoIP Communication. Integration of the iris biometric with cryptographic is well-suited for this VoIP technology, which provide a better approach for a secured transmission of packets in between one network to another network. If unfortunately the iris biometric is stolen, the intruder will not able to access the data since pseudo random numbers are fused with iris biometric. Therefore billions of unique keys can be generated, making VoIP technology hard for an attacker to guess the key.
